## ABSTRACT

Surgical treatment of coronary artery disease in the systemic lupus erythematosus (SLE) patients has not been comprehensively addressed. The present review aimed to give an overview of coronary artery disease in the SLE patients receiving coronary artery bypass grafting (CABG). The study materials were based on comprehensive literature retrieval, which recruited 17 pertinent articles with 30 patients. No differences were found in the graft patencies between the arterial and venous grafts; and between the early and late patency rates. Pathological inspections revealed that all graft vessels were normal with no signs of SLE-related atherosclerosis or vasculitis, one coronary artery was pathologically normal, and another coronary artery showed vasculitis. The coexisting disorders, including diabetes mellitus, hyperlipidemia, and nephropathy in the SLE patients cause early deterioration of the saphenous vein grafts. Early occlusion of the saphenous vein grafts was also observed in SLE patients. The left anterior descending coronary artery was most commonly affected by SLE and was the most common coronary artery requiring a CABG procedure. The graft vessels, both arterial and venous, rarely degenerated; whereas, early and late graft failure was usually caused by technical failures. The lack of vasculitis and atherosclerosis in the arterial grafts encourage surgeons to prefer to use the arterial grafts in SLE patients. Less invasive surgical technique would favour the patients in terms of long-term outcomes.

**Key Words:** *Coronary artery bypass grafting, Graft occlusion, Vascular, Systemic lupus erythematosus.*

## INTRODUCTION

Cardiovascular involvements of systemic lupus erythematosus (SLE) may include pericarditis, myocarditis, endocarditis, valvular disorders, and coronary artery disease.<sup>1</sup> Coronary artery disease is a leading cause of death of SLE patients.<sup>2</sup> It can be attributed to premature atherosclerosis, arteritis, thrombosis, embolisation, vasospasm, and impaired coronary flow reserve.<sup>3</sup> Myocardial infarction can be a presenting manifestation of SLE.<sup>4</sup>

It was reported that angina/myocardial infarction occurred in 2-16% of the patients.<sup>3</sup> A necropsy observation on 623 coronary segments from 22 necropsy patients showed that the prevalence of coronary artery stenosis of different degrees was significantly higher than that of the control.<sup>5</sup> In addition, the development of coronary artery aneurysm in SLE patients can also be a sequel of arteritis and premature atherosclerosis.<sup>4</sup>

Nevertheless, surgical treatment of coronary artery disease in SLE patients is sporadically reported and the results of coronary artery bypass grafting (CABG) in these patients are somewhat inconclusive. The present study aimed to review the available evidence on coronary artery disease in SLE patients receiving a surgical treatment.

## METHODOLOGY

The preferred reporting items for systematic reviews and meta-analyses (PRISMA) statement guidelines were followed in this meta-analysis. Publications were systematically searched in the PubMed, Highwire Press, and the Cochrane Library databases. The MeSH terms and keywords used to identify articles included systemic lupus erythematosus, coronary artery disease, myocardial infarction, coronary artery bypass grafting, off-pump coronary artery bypass, and minimally invasive direct coronary artery bypass (MIDCAB). Bibliographic references were also tracked for the completeness of the literature retrieval. Thirty-six articles were found related to the topic and keywords in the literature search; and 17 articles, which met the inclusion criteria during preliminary assessment, were included in the review. Of them, articles with a patient population receiving CABG procedure in the majority (for example, >90%) of patients and receiving CABG and concurrent valve procedures in a minority of patients were recruited into this

study. The exclusion criteria were articles describing coronary artery disease in rheumatic patients (n=5), cardiovascular risks of SLE patients (n=4), irrelevant design (n=2), gene polymorphism of SLE patients (n=2), ischemic stroke of SLE patients (n=1), hospitalisation of SLE patients receiving CABG (n=1), lupus nephritis (n=1), background discussion of SLE (n=1), cardiovascular diseases in connective tissue disorder (n=1), and cardiovascular diseases in Sjögren syndrome patients (n=1).

Data were carefully extracted for details of the study population, demographics, medical history of SLE, clinical manifestations, duration of steroid use, surgical techniques, bypass graft configurations, early (2-3 weeks after operation) and late ( $\geq 1$  year) graft patency (detected by coronary angiography), pathology of the graft vessels and coronary arteries, length of follow-up, and patients' prognoses.

Quantitative data were presented as mean  $\pm$  standard deviation, and the intergroup differences were compared by independent samples *t*-test. The categorical variables, expressed by numbers and percentages, were compared by Fisher's exact test. An IBM SPSS statistics software version 22.0 was used for the statistical analyses.  $p < 0.05$  was considered statistically significant.

## RESULTS

In total, 17 articles were obtained with 30 patients involved in the articles.<sup>4,6-20</sup> Gender was not indicated for one of the patients. Of the remaining 29 patients, 10 (34.5%) were male and 19 (65.5%) were female patients ( $\chi^2 = 5.6$ ,  $p = 0.035$ ), with a male-to-female ratio of 1:1.9. The patients were at the age of  $50.6 \pm 16.3$  years ( $n = 28$ ). There was no difference in patients' age between the male and the female patients ( $60.0 \pm 13.0$  years vs.  $51.9 \pm 13.1$  years,  $p = 0.167$ ). The SLE history of the patients lasted  $11.5 \pm 7.4$  years ( $n = 20$ ). The female patients had a longer SLE history than the male patients ( $15.4 \pm 6.9$  years vs.  $7.4 \pm 5.1$  years,  $p = 0.038$ ). The steroid use was  $12.4 \pm 4.5$  years ( $n = 8$ ) for the patients until current admissions.

Clinical manifestations for current admissions were described in 13 (43.3%) patients. There were 19 manifestations in the 13 patients, including chest pain/angina ( $n = 12$ , 63.2%),<sup>4,6,8,9,11-15,17</sup> dyspnoea/shortness of breath ( $n = 5$ , 26.3%),<sup>8,11,12,15,16</sup> epigastric pain ( $n = 1$ , 5.3%),<sup>8</sup> and numbness ( $n = 1$ , 5.3%).<sup>8</sup> One of the patients with coronary artery aneurysm of the right coronary artery developed myocardial re-infarctions.<sup>4</sup>

Surgical indication for CABG was coronary artery stenosis or occlusion in 29 (96.7%) patients; and coronary artery aneurysm associated with coronary artery stenosis in one (3.3%) patient. Two (6.7%) patients were operated on an urgent basis.<sup>8,11</sup> The number of the diseased coronary arteries was described in 23 (76.7%) patients, in whom 2-vessel disease predominated (Figure 1). The affected coronary artery was described in 17 (56.7%) patients, with the left anterior descending coronary artery being the most commonly affected coronary artery (Figure 2). The number of the bypass grafts was  $2.3 \pm 1.1$  per patient ( $n = 24$ ).

Figure 1: The distribution of the number of the diseased coronary arteries in 23 patients. LM: Left main trunk.

Figure 2: The affected coronary artery in 17 patients. LAD: left anterior descending coronary artery. LIMA: Left internal mammary artery; OM: Obtuse marginal branch; PDA: Posterior descending coronary artery; RCA: Right coronary artery.

The bypass technique was not detailed in one report for one patient. In the remaining 29 patients, the techniques were conventional CABG in 22 (75.9%) patients,<sup>4,6-10,13,15-19</sup> on-pump beating heart CABG in 3 (10.3%) patients,<sup>10</sup> off-pump coronary artery bypass in 3 (10.3%) patients,<sup>6,11,14</sup> and endoscopic coronary artery bypass in 1 (3.4%) patient.<sup>12</sup> The coronary artery bypass grafts were substantially described in 20 (66.7%) patients, in whom 45 grafts were bypassed, with 40 (88.9%) single grafts, 3 (6.7%) sequential grafts,<sup>16,18</sup> and 1 (2.2%) Y-graft.<sup>14</sup> The left internal mammary artery-left descending coronary artery bypass was the most common bypass configuration of this patient setting (28.9%, 13/45).<sup>6,11-19</sup>

**Table I: Distributions of 47 graft (donor) vessels and 51 receipt vessels for coronary artery bypass grafting.**

Vessel	n (%)
Graft (donor) vessel	
Left internal mammary artery <sup>6,7,11-19</sup>	16 (34.0)
Right internal mammary artery <sup>14,18</sup>	4 (8.5)
Right gastroepiploic artery <sup>13</sup>	1 (2.1)
Saphenous vein graft <sup>4,6,7,11,15-18</sup>	26 (55.3)
Receipt vessel	
Left anterior descending coronary artery <sup>6,8,11-19</sup>	19 (37.3)
Diagonal branch <sup>14-16,18</sup>	7 (13.7)
Circumflex branch <sup>8,18</sup>	7 (13.7)
Obtuse marginal branch <sup>6,14-17</sup>	7 (13.7)
Left main trunk <sup>8</sup>	1 (2.0)
Right coronary artery <sup>4,11,13,18</sup>	7 (13.7)
Posterior descending coronary artery <sup>15,17</sup>	3 (5.9)

**Table II: A comparison of graft patency.**

Graft patency	Early	Late	$\chi^2$	p-value
Arterial	9/11 (81.8)	7/8 (87.5)	0.1	1.000
Venous	16/18 (88.9)	6/6 (100)	0.7	1.000
Unspecified	4/7 (57.1)	1/1 (100)	0.7	1.000
Overall	29/36 (80.6)	14/15 (93.3)	1.3	0.409
$\chi^2$ (arterial vs. venous graft)	0.3	0.8	--	--
p-value (arterial vs. venous graft)	0.622	1.000	--	--

There were 47 graft vessels reported, including 21 (44.7%) arterial and 26 (55.3%) venous grafts ( $\chi^2=1.1$ ,  $p=0.409$ ). The left anterior descending coronary artery was the most common coronary artery to be bypassed (Table I).

Nine (30%) patients had one or more concurrent/subsequent/late cardiac operations, including concurrent mitral valve replacement, aortic valve replacement, or mitral/tricuspid valvuloplasty ( $n=5$ ),<sup>10,18,19</sup> apical aneurysmectomy ( $n=1$ ),<sup>9</sup> and stent deployment (to seal the coronary artery aneurysm and to dilate the stenotic lesion) ( $n=1$ ),<sup>4</sup> subsequent stent to the first diagonal branch on postoperative day 3 ( $n=1$ ),<sup>12</sup> and late aortic valve replacement three years after the initial CABG ( $n=1$ ).<sup>16</sup>

The graft patency was evaluated early in 19 patients and late in six patients. No differences were found in the graft patencies between the arterial and venous grafts or between the early and late patency rates (Table II). Twenty risk factors leading to graft failure were described in 16 (53.3%) patients, with hypertension<sup>10,12,17,18</sup> being the most common risk factor accounting for 35% (7/20), followed by renal failure (20%, 4/20),<sup>6,18</sup> diabetes mellitus (15%, 3/20),<sup>17,18</sup> antiphospholipid syndrome (10%, 2/20),<sup>14,19</sup> hypercholesterolemia (10%, 2/20),<sup>4,18</sup> positive lupus anticoagulant (5%, 1/20),<sup>19</sup> and pulmonary embolism (5%, 1/20).<sup>14</sup> The coexisting disorders, including diabetes mellitus, hyperlipidemia, and nephropathy, led to an early deterioration of the saphenous vein grafts.<sup>18</sup>

There were eight graft vessels (5 left internal mammary arteries,<sup>6,13,15</sup> one right gastroepiploic artery<sup>13</sup> and two saphenous vein grafts<sup>6</sup>) and two coronary arteries under pathological inspections in six (20%) patients. All eight graft vessels were normal with no signs of SLE-related atherosclerosis or

vasculitis, whereas one coronary artery was pathologically normal,<sup>15</sup> and another coronary artery showed changes of vasculitis.<sup>12</sup>

Patients were under a follow-up of  $34.4 \pm 31.6$  months ( $n=18$ ). The prognoses were described in 29 patients: 17 (58.6%) patients recovered,<sup>6,10,12-19</sup> 2 (6.9%) patients were improved,<sup>8,9</sup> 5 (17.2%) patients were complicated (early graft thrombosis,<sup>10</sup> bleeding,<sup>4</sup> mediastinitis,<sup>11</sup> and superficial wound abscess of the right leg with subsequent saphenous vein graft occlusion<sup>15</sup>), and 5 (17.2%) patients died.<sup>10,18,19</sup> There were 2 early deaths<sup>18,19</sup> and 3 late deaths,<sup>10,18,19</sup> with an early mortality of 6.9% (2/29), and a late mortality of 11.1% (3/27).

## DISCUSSION

The premature coronary atherosclerosis in SLE can be due to immune complex deposition and complement activation in the arterial wall, chronic steroid therapy that may worsen hyperglycemia and hyperlipidemia, and/or the associated antiphospholipid syndrome, which predisposes to thrombus formation and myocardial infarctions.<sup>12</sup> The risk factors responsible for coronary artery disease in SLE patients include coronary arteritis and steroid-induced accelerated atherosclerosis.<sup>18</sup> The SLE patients are usually young, and the acute coronary syndrome in these patients is largely attributed to the underlying autoimmune disease.<sup>12</sup> The pathological changes of the coronary arteries in SLE patients can be atherosclerosis or arteritis, and the incidence of coronary atherosclerosis and arteritis was similar.<sup>21</sup> Hyaline arteriolar diseases seen in the coronary lesions probably causes myocardial infarction.<sup>21</sup> Clinically, coronary arteritis, premature atherosclerosis, and SLE-induced myocardial microvasculopathy are considered to be the predisposing risk factors of myocardial infarction in SLE patients.<sup>14</sup> Postoperative myocardial infarction can be due to graft thrombosis that may cause patient death.<sup>19</sup>

Balloon angioplasty procedures may pose some risks to these patients, as it may dislodge the thrombus, resulting in an embolisation of the distal right coronary artery.<sup>4</sup> This event may warrant an aggressive surgical operation in SLE patients.

CABG in SLE patients was first reported by Homcy *et al.* in 1982.<sup>9</sup> In 2014, Maeda *et al.* described an SLE patient receiving an urgent CABG before the start of steroid therapy was associated with difficult perioperative management.<sup>11</sup> Therefore, perioperative administration with methylprednisolone and heparin was suggested for preventing from thrombus formation and aggravation of SLE.<sup>6</sup> Moreover, in order to obtain a better operative course, the recommended perioperative management strategies included one-week preoperative suspension of anticoagulants to avoid operative bleeding; continuous administration of heparin to prevent from thrombus formation; activated clotting time controlled for >500 seconds during the operation and methylprednisolone infusion to avoid acute aggravation of SLE; and early postoperative anticoagulant recovery.<sup>19</sup>

The SLE patients are at greater risks of postoperative morbidity

and mortality. It was reported that the in-hospital mortality rate of CABG in SLE patients was 5.7%.<sup>22</sup> This result was much higher than in-hospital mortality rate of CABG in general population reported from The Society of Thoracic Surgeons Adult Cardiac Surgery Database, which was 1.7% and 1.8% in 2016 and in 2019, respectively.<sup>23,24</sup> Papa *et al.* identified four risk factors that predicted an increased morbidity of SLE patients, which were preoperative higher doses of steroid, multiple organ involvements, emergent operation, and renal failure.<sup>25</sup> The SLE patients receiving CABG and concurrent valvular operation posed an increased risk of death.<sup>21</sup> Uea *et al.* reported a hospital death of one of their SLE patients receiving CABG was due to an urgent operation, acute heart failure, and a low ejection fraction of 26%.<sup>18</sup>

The patency rate of the arterial grafts in SLE patients receiving CABG was 81.8% (9/11) with two stenosed or string-like grafts due to intraoperative technical failures. There has been consensus on whether the arterial grafts should be preferred in SLE patients.<sup>26</sup> In general population, the patency of coronary artery bypass grafts depends on graft choices, bypass configuration, and stenotic degree and location of the target coronary arteries. In the SLE patients, both coronary arteritis and atherosclerosis have been described in young SLE patients. The SLE patients were reported to often have vasculitis; and the incidence was reported to be 11-36%.<sup>27</sup> However, pathological inspections of the mammary arterial grafts revealed only minor atherosclerotic changes in most of the SLE patients, but no arteritis or significant atherosclerosis was noted.<sup>18</sup> Ura *et al.* repeated angiography in two patients with the mammary artery grafting, which showed no signs of newly developed atherosclerosis or arteritis.<sup>18</sup> The long-term patency of mammary artery grafts was demonstrated in various studies on SLE patients, but it was uncertain whether the mammary arterial grafts would develop arteritis and atherosclerosis in SLE patients at a later stage. Long-term patency of the gastroepiploic artery graft in patients with SLE also requires further evaluations.<sup>13</sup> Moreover, the coexisting disorders, such as diabetes mellitus, hyperlipidemia, and nephropathy, often cause an early deterioration of the saphenous vein grafts in SLE patients.<sup>18</sup> Early occlusion of the saphenous vein grafts has also been observed in SLE patients.<sup>28</sup> The resistance of internal mammary artery to atherosclerosis was once attributed to prolonged steroid use in SLE patients,<sup>18</sup> but nowadays it is convinced that the advantages of the internal mammary artery grafts over other conduits are due to the superior endothelial function, greater antithrombotic molecules, higher endothelial nitric oxide production, and flow remodeling.<sup>2,29,30</sup> Most importantly, steroids, particularly long-term steroid use, inhibits the normal healing process and may predispose to aneurysmal formation in coronary artery disease patients.<sup>9</sup> This may possibly interpret the graft failure in SLE patients.

The present study revealed that both young and old patients took shorter time to develop coronary artery disease than middle-aged patients. There was no discrepancy in the patency rates between the arterial and venous grafts. It proved that the

graft vessels, both arterial and venous, rarely degenerated, and technical failures might be a major determinant of early and late graft failure.<sup>18</sup> Meanwhile, the pathological changes of the coronary artery were noted in part of SLE patients.

Patients with SLE is often associated with an antiphospholipid syndrome, a severe prothrombotic disorder that may occur after surgical operations. The SLE patients receiving a heart operation by using a minimally invasive approach may prevent severe tendency of haemorrhage in relation to anticoagulation from happening.<sup>31</sup> With hybrid CABG and coronary angioplasty, the outcomes of the SLE patients with coronary artery disease seem to be promising.<sup>18</sup>

The limited information from the pertinent literature constitutes the major drawback of this study. Comparisons of the surgical outcomes between the conventional and less invasive CABG procedures, and the graft patency rates between different grafts could not be sufficiently evaluated. Further observations of SLE patients receiving CABG are warranted for obtaining more conclusive results in terms of the graft patency, the pathological changes of the grafts and the coronary arteries, and the predisposing risk factors for graft failure of SLE patients.

## CONCLUSION

SLE patients requiring CABG are mostly ladies. The left anterior descending coronary artery is the most commonly affected coronary artery that requires CABG. Prolonged steroid use in SLE patients enables the mammary arteries resistant to the atherosclerotic changes. The graft vessels, both arterial and venous, rarely degenerated; whereas, early and late graft failure was usually caused by technical failures. The lack of vasculitis and atherosclerosis in the arterial graft vessels encourage surgeons to prefer to use the arterial grafts in SLE patients. Less invasive surgical technique would favour these patients in terms of long-term outcomes.
